

Context Debug

Executive Summary

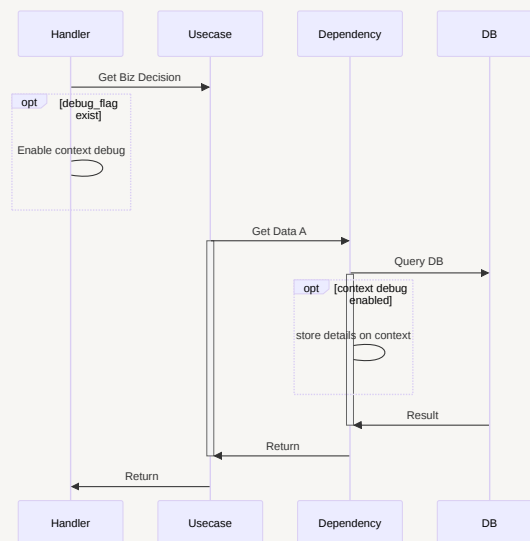

A debug tool to get details on each dependency calls (API, Data stores, etc.) through Golang context. **Only** for **debug purpose** since it the context will contain heavy data on context.

Background

As developer, it's so painful on debugging a feature with dozens downstream. Debug it one by one through find the related logs or reproduce call will be nightmare.

How It Works

Detailed Solution

Parts

1. Initiation phase (new object)

Will placed on the front endpoint layer, it will:

1. Check if debug flag is provided
2. IF on debug mode, create the object that contain:
 - a. list
 - b. mutex

2. Collector

Will placed on each dependency call

3. Snapshot

Will return all data in the list

Data Struct

```
type Entry struct {
    Name string `json:"name"`
    Request interface{} `json:"req"`
    Response interface{} `json:"resp"`
    Error error `json:"err"`
    LatencyMs int `json:"lat_ms"`
}
```

Task Breakdown

Agent: Claude Code

Task Progress

Aa Name	🕒 Status	≡ Description
<u>Core</u>	TODO	Create a core context debug lib.
